## Antibacterial Agents

This invention relates to the use of N-formyl hydroxylamine derivatives as antibacterial agents, to a novel class of such compounds, and to pharmaceutical and veterinary compositions comprising such compounds.

### Background to the Invention

In general, bacterial pathogens are classified as either Gram-positive or Gram-negative. Many antibacterial agents (including antibiotics) are specific against one or other Gram-class of pathogens. Antibacterial agents effective against both Gram-positive and Gram-negative pathogens are therefore generally regarded as having broad spectrum activity.

Many classes of antibacterial agents are known, including the penicillins and cephalosporins, tetracyclines, sulfonamides, monobactams, fluoroquinolones and quinolones, aminoglycosides, glycopeptides, macrolides, polymyxins, lincosamides, trimethoprim and chloramphenicol. The fundamental mechanisms of action of these antibacterial classes vary.

Bacterial resistance to many known antibacterials is a growing problem. Accordingly there is a continuing need in the art for alternative antibacterial agents, especially those which have mechanisms of action fundamentally different from the known classes.

Amongst the Gram-positive pathogens, such as Staphylococci, Streptococci, Mycobacteria and Enterococci, resistant strains have evolved/arisen which makes them particularly difficult to eradicate. Examples of such strains are methicillin resistant *Staphylococcus aureus* (MRSA), methicillin resistant coagulase negative Staphylococci (MRCNS), penicillin resistant *Streptococcus pneumoniae* and multiply resistant *Enterococcus faecium*.

Pathogenic bacteria are often resistant to the aminoglycoside,  $\beta$ -lactam (penicillins and cephalosporins), and chloramphenicol types of antibiotic. This resistance involves the enzymatic inactivation of the antibiotic by hydrolysis or by formation of inactive derivatives. The  $\beta$ -lactam (penicillin and cephalosporin) family of antibiotics are characterised by the presence of a  $\beta$ -lactam ring structure. Resistance to this family of antibiotics in clinical isolates is most commonly due to the production of a "penicillinase" ( $\beta$ -lactamase) enzyme by the resistant bacterium which hydrolyses the  $\beta$ -lactam ring thus eliminating its antibacterial activity.

Recently there has been an emergence of vancomycin-resistant strains of enterococci (Woodford N. 1998 Glycopeptide-resistant enterococci: a decade of experience. *Journal of Medical Microbiology*. 47(10):849-62). Vancomycin-resistant enterococci are particularly hazardous in that they are frequent causes of hospital based infections and are inherently resistant to most antibiotics. Vancomycin works by binding to the terminal D-Ala-D-Ala residues of the cell wall peptidoglycan precursor. The high-level resistance to vancomycin is known as VanA and is conferred by a genes located on a transposable element which alter the terminal residues to D-Ala-D-lac thus reducing the affinity for vancomycin.

In view of the rapid emergence of multidrug-resistant bacteria, the development of antibacterial agents with novel modes of action that are effective against the growing number of resistant bacteria, particularly the vancomycin resistant enterococci and  $\beta$ -lactam antibiotic-resistant bacteria, such as methicillin-resistant *Staphylococcus aureus*, is of utmost importance.

#### Brief Description of the Invention

This invention is based on the finding that certain N-formyl hydroxylamine derivatives have antibacterial activity, and makes available a new class of antibacterial agents. The inventors have found that the compounds with which this invention is concerned are antibacterial with respect to a range of Gram-positive and Gram-negative organisms. Furthermore, there is evidence that some compounds

are antibacterial with respect to bacteria which are resistant to commonly used antibiotics such as vancomycin and the  $\beta$ -lactam antibiotics, for example methicillin-resistant *Staphylococcus aureus*.

Although it may be of interest to establish the mechanism of action of the compounds with which the invention is concerned, it is their ability to inhibit bacterial growth which makes them useful. However, it is presently believed that their antibacterial activity is due, at least in part, to intracellular inhibition of bacterial polypeptide deformylase (PDF) enzyme.

Bacterial polypeptide deformylases (PDF) (EC 3.5.1.31), are a conserved family of metalloenzymes (Reviewed: Meinnel T, Lazennec C, Villoing S, Blanquet S, 1997, Journal of Molecular Biology 267, 749-761) which are essential for bacterial viability, their function being to remove the formyl group from the N-terminal methionine residue of ribosome-synthesised proteins in eubacteria. Mazel et al. (EMBO J. 13(4):914-923, 1994) have recently cloned and characterised an *E. coli* PDF. As PDF is essential to the growth of bacteria and there is no eukaryotic counterpart to PDF, Mazel et al. (ibid), Rajagopalan et al. (J. Am. Chem. Soc. 119:12418-12419, 1997) and Becker et al., (J. Biol Chem. 273(19):11413-11416, 1998) have each proposed that PDF is an excellent anti-bacterial target.

Certain N-formyl hydroxylamine derivatives have previously been claimed in the patent publications listed below, although very few examples of such compounds have been specifically made and described:

EP-B-0236872	(Roche)
WO 92/09563	(Glycomed)
WO 92/04735	(Syntex)
WO 95/19965	(Glycomed)
WO 95/22966	(Sanofi Winthrop)
WO 95/33709	(Roche)

WO 96/23791	(Syntex)
WO 96/16027	(Syntex/Agouron)
WO 97/03783	(British Biotech)
WO 97/18207	(DuPont Merck)
WO 98/38179	(GlaxoWellcome)
WO 98/47863	(Labs Jaques Logeais)

The pharmaceutical utility ascribed to the N-formyl hydroxylamine derivatives in those publications is the ability to inhibit matrix metalloproteinases (MMPs) and in some cases release of tumour necrosis factor (TNF), and hence the treatment of diseases or conditions mediated by those enzymes, such as cancer and rheumatoid arthritis. That prior art does not disclose or imply that N-formyl hydroxylamine derivatives have antibacterial activity.

In addition to these, US-A-4,738,803 (Roques et al.) also discloses N-formyl hydroxylamine derivatives, however, these compounds are disclosed as enkephalinase inhibitors and are proposed for use as antidepressants and hypotensive agents. Also, WO 97/38705 (Bristol-Myers Squibb) discloses certain N-formyl hydroxylamine derivatives as enkephalinase and angiotensin converting enzyme inhibitors. This prior art does not disclose or imply that N-formyl hydroxylamine derivatives have antibacterial activity either.

(ID)

wherein:

$R_3$  represents hydrogen and  $R_4$  represents the side chain of a natural or non-natural alpha amino acid or  $R_3$  and  $R_4$  when taken together with the nitrogen and carbon atoms to which they are respectively attached form an optionally substituted saturated heterocyclic ring of 5 to 8 atoms which ring is optionally fused to a carbocyclic or second heterocyclic ring,

$R_5$  and  $R_6$ , independently represent hydrogen, or optionally substituted  $C_1$ - $C_8$  alkyl, cycloalkyl, aryl, aryl( $C_1$ - $C_8$  alkyl), heterocyclic, or heterocyclic( $C_1$ - $C_8$  alkyl), or  $R_5$  and  $R_6$  when taken together with the nitrogen atom to which they are attached form an optionally substituted saturated heterocyclic ring of 3 to 8 atoms which ring is optionally fused to a carbocyclic or second heterocyclic ring, and

According to a preferred embodiment, the various aspects of the invention can be applied against vancomycin-, quinolone- and "β-lactam"-resistant bacteria and the infections they cause.

On the hypothesis that the compounds (I) act by inhibition of intracellular PDF, the most potent antibacterial effect may be achieved by using compounds which efficiently pass through the bacterial cell wall. Thus, compounds which are highly active as inhibitors of PDF in vitro and which penetrate bacterial cells are preferred for use in accordance with the invention. It is to be expected that the antibacterial potency of compounds which are potent inhibitors of the PDF enzyme in vitro, but are poorly cell penetrant, may be improved by their use in the form of a prodrug, ie a structurally modified analogue which is converted to the parent molecule of formula (I), for example by enzymic action, after it has passed through the bacterial cell wall.

Likewise, in the side chains of non-natural alpha amino acids which contain

functional substituents, for example amino, carboxyl, hydroxy, mercapto, guanidyl, imidazolyl, or indolyl groups, such functional substituents may optionally be protected.

The term "protected" when used in relation to a functional substituent in a side chain of a natural or non-natural alpha-amino acid means a derivative of such a substituent which is substantially non-functional. The widely used handbook by T. W. Greene and P. G. Wuts "Protective Groups in Organic Synthesis" Second Edition, Wiley, New York, 1991 reviews the subject. For example, carboxyl groups may be esterified (for example as a C<sub>1</sub>-C<sub>6</sub> alkyl ester), amino groups may be converted to amides (for example as a NHCOC<sub>1</sub>-C<sub>6</sub> alkyl amide) or carbamates (for example as an NHC(=O)OC<sub>1</sub>-C<sub>6</sub> alkyl or NHC(=O)OCH<sub>2</sub>Ph carbamate), hydroxyl groups may be converted to ethers (for example an OC<sub>1</sub>-C<sub>6</sub> alkyl or a O(C<sub>1</sub>-C<sub>6</sub> alkyl)phenyl ether) or esters (for example a OC(=O)C<sub>1</sub>-C<sub>6</sub> alkyl ester) and thiol groups may be converted to thioethers (for example a tert-butyl or benzyl thioether) or thioesters (for example a SC(=O)C<sub>1</sub>-C<sub>6</sub> alkyl thioester).

There are several actual or potential chiral centres in the compounds according to the invention because of the presence of asymmetric carbon atoms. The presence of several asymmetric carbon atoms gives rise to a number of diastereoisomers with R or S stereochemistry at each chiral centre. The invention includes all such diastereoisomers and mixtures thereof. Currently, the preferred stereoconfiguration of the carbon atom carrying the R<sub>2</sub> group is R; that of the carbon atom carrying the R<sub>4</sub> group (when asymmetric) is S; and that of the carbon atom carrying the R<sub>1</sub> group (when asymmetric) is R.

In the compounds of formula (I) as defined above for use according to the invention, and in the novel compounds of the invention of formula (II) as defined above (but subject to the provisos therein):

R<sub>1</sub> may be, for example, hydrogen, methyl, or trifluoromethyl. Hydrogen is currently

preferred.

R<sub>2</sub> may be, for example:

optionally substituted C<sub>1</sub>-C<sub>8</sub> alkyl, C<sub>3</sub>-C<sub>6</sub> alkenyl, C<sub>3</sub>-C<sub>6</sub> alkynyl or cycloalkyl;

optionally substituted in the phenyl ring;

cycloalkyl(C<sub>1</sub>-C<sub>6</sub> alkyl)-, cycloalkyl(C<sub>3</sub>-C<sub>6</sub> alkenyl)- or cycloalkyl(C<sub>3</sub>-C<sub>6</sub> alkynyl)-

alkynyl)- optionally substituted in the heterocyclyl ring; or

The finding that compounds with PDF inhibitory activity can inhibit or prevent bacterial growth, opens up a novel approach for identifying new antibacterial agents by screening test compounds for activity as inhibitors of PDF *in vitro*, followed by confirmation of their antibacterial ability using bacterial growth inhibition studies. This finding also makes available (i) the use of compounds with PDF inhibitory activity as antibacterial agents, and (ii) a method for the treatment of bacterial infection or contamination by applying or administering a compound which inhibits the activity of bacterial PDF.

According to a further aspect of the invention therefore, there is provided a method for the identification of antibacterial compounds, comprising screening test compounds for their ability to inhibit PDF *in vitro*, selecting those compounds which exhibit said ability and testing these for their ability to inhibit bacterial growth. The ability to inhibit bacterial growth can be performed using classical plate or broth

culture bacterial growth inhibition studies, such as those performed in the Biological Examples herein.

A suitable *in vitro* PDF inhibition screen may comprise mixing together PDF, a PDF substrate, preferably, labelled with a detectable marker, and the test compound and assessing after a suitable length of time whether or not the presence of the test compound inhibits the ability of PDF to deformylate the substrate.

In a preferred embodiment, the cleaved substrate is detected with a fluorogenic marker such as fluorescamine. On removal of the formyl group from the N-terminal methionine of the PDF substrate, the free amino group reacts with fluorescamine generating a fluorescent product.

An alternative screen involves assessing whether a protein expressed by bacteria that express endogenous (or recombinantly expressed) PDF, when grown in the presence of a test compound, yields suitable substrate for N-terminal sequencing, or yields a lesser amount of substrate, than protein expressed from the same bacteria grown in the absence of the test compound. Such a method could be based on that used in the Biological Examples herein.

The person skilled in the art will be able to develop, without inventive input, alternative methods for screening test compounds for their ability to inhibit bacterial PDF.

The natural antibiotic actinonin (see for example J.C.S Perkin I, 1975, 819) is a hydroxamic acid derivative of Structure (A):

In addition to actinonin, various structural analogues of actinonin have also been shown to have antibacterial activity (see for example Broughton et al. (Devlin et al. Journal of the Chemical Society. Perkin Transactions 1 (9):830-841, 1975; Broughton et al. Journal of the Chemical Society. Perkin Transactions 1 (9):857-860, 1975)

To date, however, the mechanism underlying the antibacterial activity of actinonin has not been known. The present inventors have found that actinonin inhibits the activity of bacterial PDF.

The matlystatin group of compounds share a number of structural similarities with actinonin. Both are peptidic molecules with functional hydroxamic acid metal binding groups (Ogita et al., J. Antibiotics. 45(11):1723-1732; Tanzawa et al., J. Antibiotics. 45(11):1733-1737; Haruyama et al., J. Antibiotics. 47(12):1473-1480; Tamaki et al., J. Antibiotics. 47(12):1481-1492). The matlystatins and their close structural analogues are characterised by the presence in the molecule of a divalent piperazin-1, 6-diyl group, i.e.

In view of their close structural similarity to actinonin, the observation that actinonin inhibits PDF implies that matlystatin compounds may also inhibit PDF.

According to a further aspect of the present invention there is provided the use of a compound which inhibits the activity of bacterial PDF, in the preparation of an antibacterial composition or agent, provided that (i) the compound is not of formula (XI)

wherein,

- (a) R is a cyclic amino group, W is hydrogen, methyl, isopropyl, isobutyl or benzyl, and Y is hydrogen, C<sub>1</sub>-C<sub>6</sub> alkyl, phenyl, benzyl, 4-chlorophenylmethyl, 4-nitrophenylmethyl, or 4-aminophenylmethyl; or,
- (b) R is 2-pyridylamino or 2-thiazolylamino, W is isopropyl and Y is n-pentyl; or,
- (c) R is diethylamino, W is methyl or isopropyl and Y is n-pentyl;

or (ii) the compound is not one containing a divalent piperazin-1, 6-diyl group, i.e. a group of formula (XII):

According to a further aspect of the invention there is provided a method of treating bacterial infection or contamination by administering to a patient suffering such infection or contamination, or applying to the site of such infection or contamination, an antibacterially effective amount of a compound which inhibits the activity of bacterial PDF enzyme, provided that the compound is not one provided in the provisos in the immediately preceeding paragraph.

These provisos exclude actinonin and its antibacterially active analogues as disclosed in Devlin et al., Journal of the Chemical Society. Perkin Transactions 1 (9):830-841, 1975 and Broughton et al. Journal of the Chemical Society. Perkin Transactions 1 (9):857-860, 1975, and the matlystatin compounds disclosed in Ogita et al., J. Antibiotics. 45(11):1723-1732; Tanzawa et al., J. Antibiotics. 45(11):1733-1737; Haruyama et al., J. Antibiotics. 47(12):1473-1480 and Tamaki et al., J. Antibiotics. 47(12):1481-1492.

### **Method I**

A synthetic route to the title compound is outlined in Scheme 2 and is described in detail below.

Scheme 2<sup>41</sup>

**Step A: 2RS-Formyl-heptanoic acid ethyl ester**

Sodium metal (4.38 g, 0.191 mmol) was cut into small pieces and placed in a two-neck oven-dried round bottom flask under a blanket of argon. Anhydrous diethyl ether (100 ml) was added and the suspension was stirred and cooled to 0°C. The flask was fitted with a reflux condenser before dropwise addition of ethanol (1.03 ml, 17.3 mmol). A mixture of ethyl formate (15.41 g, 0.208 mmol) and ethyl caproate (25 g, 0.173 mmol) was added dropwise via a dropping funnel over a period of about 20 minutes. The resulting orange suspension (sodium metal still visible) was allowed to warm to room temperature and stirred overnight. The resulting thick orange suspension (no sodium metal visible) was cooled to 0 °C and diluted with ice-cold water (100 ml). The mixture was transferred to a separating funnel and the aqueous phase was removed, washed with diethyl ether, cooled to 0 °C and acidified with 1 M hydrochloric acid (200 ml). The emulsion was extracted with ethyl acetate and the organic layer was separated, washed with brine, dried over anhydrous magnesium sulfate and filtered. The filtrate was concentrated under reduced pressure to give a yellow oil containing primarily the title compound (11.09 g), which was used without further purification in Step B.

**Step B: 2RS-(Benzyloxyimino-methyl)-heptanoic acid ethyl ester**

The crude Claisen product from Step A (11.0 g, 63.9 mmol) was dissolved in ethanol (100 ml) and water (10 ml) and cooled to 0 °C during the addition of sodium acetate (6.2 g, 76.6 mmol) and O-benzyl hydroxylamine hydrochloride (12.23 g, 76.6 mmol). The mixture was allowed to warm to room temperature and stirred overnight. The resulting suspension was filtered and the filtrate was concentrated under reduced pressure. The residual yellow paste was partitioned between ethyl acetate and water. The organic layer was washed with 1 M hydrochloric acid and brine, dried over anhydrous magnesium sulfate, filtered and evaporated to a yellow oil. The desired product was obtained by flash chromatography (silica gel, gradient elution with 10% to 25% ethyl acetate in hexane). Yield 9.19 g (52%). <sup>1</sup>H-NMR: δ (CDCl<sub>3</sub>,

mixture of *syn*- and *anti*-isomers), 7.46 (0.6H, d, J = 8.0 Hz), 7.38-7.28 (5H, m), 6.79 (0.4H, d, J = 7.1 Hz), 5.11 (0.8H, s), 5.08 (1.2H, s), 4.16 (1.2H, q, J = 7.0 Hz), 4.13 (0.6H, q, J = 7.0 Hz), 3.91 (0.4H, q, J = 7.2 Hz), 3.21 (0.6H, td, J = 8.0 and 6.1 Hz), 1.90-1.48 (2H, m), 1.37-1.20 (7H, m), 0.87 (3H, t, J = 7.0 Hz).

Step C: 2RS-(Benzyloxyimino-methyl)-heptanoic acid

2RS-(Benzyloxyimino-methyl)-heptanoic acid ethyl ester (7.0 g, 25.24 mmol) was dissolved in methanol (125 ml) and the solution was cooled to 0 °C. 1 M Sodium hydroxide (26 ml, 26 mmol) was added in portions over 2 minutes to give a pale yellow emulsion. Additional methanol was added until a clear solution was obtained. The solution was allowed to stir for 90 minutes at 0°C then for 5 hours at room temperature whereupon TLC analysis suggested that all of the starting material had been consumed. The solvent was removed under reduced pressure and the residue was partitioned between water and ethyl acetate. The aqueous layer was cooled to 0 °C and acidified with 1 M hydrochloric acid. The emulsion thus formed was extracted twice with ethyl acetate. The combined organic extracts were washed with brine, dried over anhydrous magnesium sulfate and filtered. The filtrate was concentrated under reduced pressure to provide the title compound as a yellow oil (5.15 g, 82%) which was used without further purification in Step D. <sup>1</sup>H-NMR: δ (CDCl<sub>3</sub>, mixture of *syn*- and *anti*- isomers), 8.00 (1H, br s), 7.46 (0.6H, d, J = 7.9 Hz), 7.36-7.24 (5H, m), 6.80 (0.4H, d, J = 7.0 Hz), 5.13 (0.8H, s), 5.09 (1.2H, s), 3.94 (0.4H, q, J = 7.1 Hz), 3.27 (0.6H, td, J = 6.4 and 8.0 Hz), 1.94-1.58 (2H, m), 1.48-1.24 (4H, m) and 0.94-0.84 (3H, m).

Step D: 2RS-(Benzyloxyimino-methyl)-heptanoic acid (1S-dimethylcarbamoyl-2,2-dimethyl-propyl) amide

2-(Benzyloxyimino-methyl)-heptanoic acid (5.16 g, 20.7 mmol), *tert*-leucine N,N-dimethylamide (3.60g, 22.77mmol) and EDC (4.76g, 24.84 mmol) were stirred together in DMF (75 ml) and cooled to 0 °C. HOAt (250 mg, cat.) was added and

the bright yellow mixture was allowed to warm to room temperature and stirred overnight. The solvent was removed under reduced pressure and the residual oil was partitioned between ethyl acetate and 1M hydrochloric acid. The organic layer was washed with brine, dried over anhydrous magnesium sulfate, filtered and concentrated to dryness under reduced pressure. ## Step A: 2-Butyl acrylic acid

To a solution of n-butylmalonic acid (17.2 g, 107 mmol) in ethanol (200 ml) was added piperidine (12.76 ml, 129 mmol) and 37% aq. formaldehyde (40.3 ml, 538 mmol). The solution was heated to 80 °C during which time a precipitate appeared and then gradually redissolved over 1 hour. The reaction mixture was stirred at 80 °C overnight then cooled to room temperature. The solvents were removed under reduced pressure and the residue was dissolved in ethyl acetate (200 ml), washed successively with 1 M hydrochloric acid and brine, dried over anhydrous magnesium sulfate and filtered. The filtrate was concentrated to give the title compound as a clear oil (13.37 g, 97%). <sup>1</sup>H-NMR;  $\delta$  (CDCl<sub>3</sub>), 6.29 (1H, s), 5.65 (1H, s), 2.34-2.28 (2H, m), 1.54-1.26 (4H, m) and 0.94 (3H, t, J=7.1 Hz).

Triethylamine (30 ml, 218 mmol) and pivaloyl chloride (21ml, 168mmol) were added at such a rate that the temperature remained below -60 °C. The mixture was stirred at -78 °C for 30 minutes, warmed to room temperature for 2 hours and finally cooled back to -78 °C.

In a separate flask, 4S-benzyl-5,5-dimethyl-oxazolidin-2-one was dissolved in dry THF (500ml) and cooled to -78 °C under a blanket of argon. n-Butyllithium (2.4 M solution in hexanes, 83 ml, 200 mmol) was added slowly and the mixture was stirred for 30 minutes at room temperature. The solvents were removed under reduced pressure, the residue was redissolved in ethyl acetate and the solution was extracted with saturated aqueous sodium hydrogen carbonate (4x20 ml). The combined aqueous layers were washed with ethyl acetate (20 ml) then acidified with 1 M hydrochloric acid. The resulting suspension was extracted into dichloromethane and the solution was dried over anhydrous magnesium sulfate, filtered and evaporated to provide the title compound as a white solid (3.76 g, 52%). <sup>1</sup>H-NMR;  $\delta$  (CDCl<sub>3</sub>), 9.89 (1H, br s), 6.35 (1H, s), 5.77 (1H, s), 3.39 (2H, s), 2.49 (2H, dd, J=7.4, 14.5 Hz) and 1.25 (3H, t, J=5.2 Hz).

Triethylamine (4.6 ml, 33.5 mmol) and pivaloyl chloride (3.17 ml, 25.8 mmol) were added at such a rate that the temperature remained below -60 °C. The mixture was stirred at -78 °C for 30 minutes, warmed to room temperature for 2 hours and finally cooled back to -78 °C.

In a separate flask, 4S-benzyl-5,5-dimethyl-oxazolidin-2-one was dissolved in dry THF (75 ml) and cooled to -78 °C under a blanket of argon. n-Butyllithium (2.4M solution in hexanes, 12.9 ml, 30.9 mmol) was added slowly and the mixture was stirred for 30 minutes at room temperature. ## Step A: 4-Benzyl-3-hexanoyl-oxazolidin-2-one

4S-Benzyl-oxazolidin-2-one (14.5 g, 81.7 mmol) was dissolved in dry THF (75 ml) under an argon atmosphere. The solution was cooled in an ice bath before slow addition of n-butyllithium (1.6 M in hexanes, 56 ml, 89.2 mmol). The lithium salt crystallised from the solution as a solid mass and was allowed to warm to room temperature overnight. The resulting orange suspension was cooled again in an ice bath during the addition of a cold solution of hexanoyl chloride (10.4 ml, 74.3 mmol) in dry THF (50 ml). The mixture was left to warm to room temperature and was then stirred for 3 hours. The reaction was quenched with 1M sodium carbonate solution (5 ml) and the solvent was removed under reduced pressure. The residue was partitioned between 1 M sodium carbonate (100 ml) and ethyl acetate (150 ml). The organic layer was removed and the aqueous layer was extracted with more ethyl acetate. The combined organic layers were washed successively with water, 1 M sodium carbonate and brine, dried over anhydrous magnesium sulphate and filtered. The filtrate was concentrated to leave an orange oil. Purification by flash chromatography afforded the title compound as a yellow oil (10.21 g, 50%).  
<sup>1</sup>H-NMR;  $\delta$  (CDCl<sub>3</sub>), 7.38-7.24 (3H, m), 7.24-7.16 (2H, m), 4.68 (1H, m), 4.24-4.12 (2H, m), 3.30 (1H, dd, J=13.4, 3.2 Hz), 3.02-2.86 (2H, m), 2.77 (1H, dd, J=13.4, 9.6 Hz), 1.77-1.63 (2H, m), 1.44-1.30 (4H, m) and 0.92 (3H, br t, J=6.9 Hz).

## Step B: 1-(4S-Benzyl-2-oxo-oxazolidin-3-yl)-2R-butyl-butane-1,3-dione

4-Benzyl-3-hexanoyl-oxazolidin-2-one (10.2g, 37.1 mmol) was dissolved in THF (150ml) under an argon atmosphere and cooled to -78 °C. Lithium hexamethyldisilazide (1 M in THF, 41 ml, 41 mmol) was added *via* a cannula over a few minutes and the resulting green solution was stirred at -78°C for 2 hours. Acetyl chloride (3.3 ml, 46.3 mmol) was added slowly and the reaction mixture was stirred for 3.5 hours. A solution of citric acid (3.0 g, 14 mmol) in water (15 ml) was added quickly to quench the reaction. The solvent was removed under reduced pressure and the residue was partitioned between ethyl acetate and water, washed with brine,

dried over anhydrous magnesium sulphate and filtered. The filtrate was concentrated to provide the title compound as a yellow oil (12.11 g, contains residual solvent) which was used without further purification in Step C. <sup>1</sup>H-NMR;  $\delta$  (CDCl<sub>3</sub>), 7.37-7.21 (5H, m), 4.68 (1H, m), 4.53 (1H, dd, J=9.6, 3.7 Hz), 4.23-4.13 (2H, m), 3.43 (1H, dd, J=13.5, 3.3 Hz), 2.75 (1H, dd, J=13.5, 9.9 Hz), 2.33 (3H, s), 2.03 (1H, m), 1.77 (1H, m), 1.46-1.26 (4H, m) and 0.98-0.86 (3H, m).

Step C: 1-(4S-Benzyl-2-oxo-oxazolidin-3-yl)-2R-butyl-butane-1,3-dione 3-(O-benzyl-oxime)

To a solution of 1-(4S-benzyl-2-oxo-oxazolidin-3-yl)-2R-butyl-butane-1,3-dione (12.11g, 38.15mmol) in water (10ml) and ethanol (90ml) was added sodium acetate (3.75g, 45.78mmol) and O-benzyl hydroxylamine hydrochloride (7.31g, 45.78mmol). The resulting suspension was left to stir at room temperature overnight. The product (7.3g, 45%, single oxime isomer) crystallised directly from the reaction and was filtered, washed with aqueous ethanol (1:1) and dried under vacuum. Further material (5.31 g, 33%, mixture of oxime isomers) was obtained as a yellow oil from the mother liquors by acid-base extraction followed by column chromatography. <sup>1</sup>H-NMR;  $\delta$  (CDCl<sub>3</sub>, major oxime isomer), 7.34-7.20 (8H, m), 7.12-7.07 (2H, m), 5.14-5.02 (2H, m), 4.53 (1H, m), 4.13 (1H, dd, J=9.4, 4.0 Hz), 4.04 (1H, br t, J=8.4 Hz), 3.91 (1H, dd, J=9.0, 2.7 Hz), 3.16 (1H, dd, J=13.4, 2.9 Hz), 2.09 (3H, s), 1.97 (1H, m), 1.75 (1H, dd, J=13.4, 10.8 Hz), 1.67 (1H, m), 1.45-1.22 (4H, m) and 0.91 (3H, br t, J=6.9 Hz).

Step D: 4S-Benzyl-3-[2R-(1R (or S)-benzyloxyamino-ethyl)-hexanoyl]-oxazolidin-2-one

The mixture of oximes from Step C (5.31 g, 12.5 mmol) was dissolved in acetic acid (30 ml) and cooled in an ice-water bath before addition of sodium cyanoborohydride (0.8 g, 12.5 mmol) in one portion. Effervescence subsided after a few minutes and a further portion of borohydride (0.8 g) was added. The reaction was allowed to

warm to room temperature and stirred overnight. The acetic acid was removed under reduced pressure and the residue was azeotroped with toluene. The resulting oil was dissolved in ethyl acetate, washed with water, 1 M sodium carbonate and brine, dried over anhydrous magnesium sulphate and filtered. The filtrate was evaporated to leave a pale yellow oil which was purified by flash chromatography (silica gel, 10% to 25% ethyl acetate in hexane as eluant). Yield 3.43 g, 64%).

<sup>1</sup>H-NMR;  $\delta$  (CDCl<sub>3</sub>, mixture of  $\alpha$ -diastereoisomers), 7.36-7.17 (10H, m), 5.80 (0.45H, br s), 5.55 (0.55H, br d, J=8.9 Hz), 4.72-4.59 (3H, m), 4.20-4.05 (2H, m), 3.97 (0.45H, m), 3.82 (0.55H, m), 3.47-3.22 (2H, m), 2.45 (1H, m), 1.90-1.48 (2H, m), 1.40-1.14 (7H, m) and 0.95-0.84 (3H, m).

Step E: N-[2R-(4S-Benzyl-2-oxo-oxazolidine-3-carbonyl)-1R (or S)-methyl-hexyl]-N-benzyloxy- formamide

4S-Benzyl-3-[2R-(1R (or S)-benzyloxyamino-ethyl)-hexanoyl]-oxazolidin- 2-one (3.08 g, 7.3 mmol) was dissolved in dry THF and treated with N-formylbenzotriazole (1.60 g, 10.9 mmol). The reaction was stirred for 4 hours at room temperature. The solvent was removed under reduced pressure and the remaining oil was partitioned between dichloromethane (40 ml) and 1 M sodium hydroxide solution (30 ml). The organic layer was removed, washed with more sodium hydroxide then brine, dried over anhydrous magnesium sulphate, filtered and evaporated. Purification by flash chromatography (silica gel, 20% to 50% ethyl acetate in hexane) gave the title compound as a pale yellow solid (2.50 g, 76%). <sup>1</sup>H-NMR;  $\delta$  (CDCl<sub>3</sub>, mixture of  $\alpha$ -diastereoisomers and rotamers), 8.22 (1H, br m), 7.54-7.13 (10H, m), 5.22-3.92 (7H, br m), 3.30 (1H, m), 2.48 (1H, br m), 1.85-1.13 (9H, br m) and 0.93-0.83 (3H, m).

solution (27% w/w), 13.26 mmol) was added followed immediately by lithium hydroxide (167 mg, 3.98 mmol). The reaction was allowed to warm to room temperature and stirred for a further 3 hours. The solution was cooled again before addition of sodium nitrite (0.92 g, 13.3 mmol). After 10 minutes, most of the solvent was removed under reduced pressure to leave a white paste which was partitioned between ethyl acetate (25 ml) and 1M sodium carbonate (30 ml). The organic layer was washed with more sodium carbonate solution and the combined aqueous extracts were washed with ethyl acetate. The aqueous layer was cooled and acidified with 1 M hydrochloric acid and extracted twice with ethyl acetate. The combined organic layers were washed with brine, dried over anhydrous magnesium sulphate, filtered and evaporated to provide the title compound as a green oil (839 mg, 86%). <sup>1</sup>H-NMR;  $\delta$  (CDCl<sub>3</sub>, mixture of  $\alpha$ -diastereoisomers and rotamers), 8.40-7.64 (2H, br m), 7.48-7.27 (5H, m), 5.23-4.80 (2H, m), 4.16 (1H, br m), 2.79 (1H, m), 1.67-1.47 (2H, m), 1.47-1.18 (7H, m) and 0.95-0.82 (3H, m).

2R-[1R (or S)-(Benzyloxy-formyl-amino)-ethyl]-hexanoic acid (839 mg, 2.86 mmol), tert-leucine N,N-dimethyl amide (498 mg, 3.15 mmol) and EDC (658 mg, 3.43 mmol) were dissolved together in DMF (15 ml) and a catalytic amount of HOAt (60 mg) was added. The solution was left to stir for several days at room temperature. The solvent was removed under reduced pressure and the remaining oil was partitioned between ethyl acetate and 1 M hydrochloric acid (75 ml). The organic layer was washed successively with 1 M hydrochloric acid, 1 M sodium carbonate and brine, dried over anhydrous magnesium sulphate filtered and evaporated to leave a yellow foam (1.08 g, 82%). <sup>1</sup>H-NMR;  $\delta$  (CDCl<sub>3</sub>, mixture of  $\alpha$ -diastereoisomers and rotamers), 8.13 (1H, br m), 7.52-7.31 (5H, m), 6.28 (1H, br m), 5.36-4.67 (3H, br m), 4.09 (1H, br m), 3.14 (3H, s), 2.95 (1.2H, s), 2.93 (1.8H, s), 2.48 (1H, br m), 1.61-1.04 (9H, m), 0.99 (3.6H, s), 0.95 (5.4H, s) and 0.89-0.75 (3H, m).

Biological Example Bi) *Cloning of the Escherichia coli PDF gene.*

The *E. coli* PDF gene was cloned in pET24a(+) (designated pET24-PDF) and was used to transform BL21 DE3 cells from Novagen Inc, (Madison, Wisconsin). Clones were selected at 37°C on YT agar plates (8g/l typtone, 5g/yeast extract, NaCl 5g/l, agar 15g/l) supplemented with 30µg/ml kanamycin.

ii) *Expression of PDF*

A 20ml overnight culture of BL21 DE3 cells harbouring pET24-PDF was used to infect 500ml 2xYT broth (16g/l typtone, 10g/l yeast extract, NaCl 5g/l) containing 30ug/ml kanamycin in a 2 litre baffled flask and grown at 37°C with shaking to an OD<sub>600</sub> 0.6. The culture was then induced by adjusting the medium to 1.0mM isopropyl β-D thiogalactopyranoside (IPTG). The induction was allowed to proceed for a further 3 hours at 37°C, the cells were harvested by centrifugation and the cell pellet washed with 250ml phosphate buffered saline (PBS) and the pellet stored at -70°C.

iii) *Preparation of soluble protein fraction.*

The cells from a 1 litre expression were resuspended in 2x 25ml of ice cold phosphate buffered saline. The cell suspension was sonicated on ice using an MSE Soniprep 150 fitted with a medium probe and at an amplitude of 20-25 microns in 6x20 second pluses. The resulting suspension was then cleared by centrifugation at 20,000 xg for 15 minutes. The supernatant was then used for further purification of the enzyme.

iv) *PDF Purification*

*E. coli* lysate from a 1l culture in phosphate buffered saline (PBS) were adjusted to 2M ammonium sulphate. A 15ml phenyl sepharose column was equilibrated with PBS/2M ammonium sulphate at 4°C. The lysate was loaded on the column and washed with equilibration buffer. The column was eluted by reducing the ammonium sulphate concentration from 2M to 0M over 10 column volumes. 5ml fractions were collected and analysed by SDS-PAGE. The fractions containing the majority of the 20kDa PDF were pooled. The pooled fractions were concentrated using a 3kDa cutoff membrane to a volume of 5ml. The fraction was then loaded onto a Superdex 75 (size exclusion chromatography) column equilibrated in PBS. The concentrated PDF pool eluted at one ml/min at 4°C and 5ml fractions collected and analysed by SDS-PAGE. The purest fractions were pooled and stored at -70°C.

(v) *PDF in vitro assay*

The assay was performed in a single 96 well plate in a final volume of 100µl containing:

- 20µl PDF (4µg/ml)
- 20µl 100mM Hepes pH 7.0 + 1M KCl + 0.05% Brij
- 10µl serial dilution of test compound in 20% DMSO
- 50µl formyl-Met-Ala-Ser (8mM)

The assay was incubated at 37°C for 30 minutes. The free amino group of the deformylated (Met-Ala-Ser) product was detected using fluorescamine, by the following additions:

- 50µl 0.2M borate pH 9.5
- 50µl fluorescamine (150µg/ml in dry dioxane)

Fluorescence was quantified on SLT Fluostar plate reader using an excitation wavelength of 390nm and an emission wavelength of 485nm. Standard control

reactions are a no inhibitor reaction which provides the zero inhibition figure and a no enzyme and no inhibitor reaction which provides the 100% inhibition figure. The data was analysed by conversion of the fluorescence units to % inhibition and the inhibitor concentration plotted against % inhibition. The data was fitted to a sigmoidal function :  $y = A + ((B - A) / (1 + ((C/x)^D)))$ , wherein A represents zero inhibition, B represents 100% inhibition and C represents the  $IC_{50}$ , D represents the slope. The  $IC_{50}$  represents the concentration of inhibitor (nM) required to decrease enzyme activity by 50%.

Compounds of the invention were found to inhibit bacterial PDF *in vitro*. In addition, actinonin (Sigma Cat. No. A-6671) was also found to inhibit bacterial PDF *in vitro*.

#### Biological Example C

*Demonstration that compound 2 inhibits PDF in vivo.*

1     *Blocking the tRNA<sup>i</sup>-Met formylation reaction confers resistance to Compound 2 (diastereomer/isomer A).*

Trimethoprim specifically inhibits dihydrofolate reductase, thereby depressing the pools of tetrahydrofolate (THF) derivatives, including formyl tetrahydrofolate (fTHF), the substrate of the methionyl-tRNA formyltransferase (EC 2.1.2.9). If all essential metabolites whose biosynthesis involves THF derivatives, eg pantothenate, methionine, glycine, purine nucleotides and thymidine are supplied exogenously in the form of precursor compounds in rich medium supplemented with thymidine, then bacteria grown in rich medium plus thymidine (0.3mM) and trimethoprim (100µg/ml) can synthesize all the chemical components of normal cells except f-Met-tRNA<sup>i</sup> (Baumstark *et al.*, J. Bacteriol. 129:457-471, 1977). Unformylated Met-tRNA<sup>i</sup> is used instead, resulting in the formation of polypeptides devoid of a formyl group at their N-terminus, independently of the action of deformylase. As predicted by the inventors, DH5α cells grown in LB medium (typtone 10g/l, yeast extract 5g/l NaCl 10g/l pH7.5) supplemented with trimethoprim and thymidine, were found to be resistant to

compound 2 (diastereomer A). The demonstration that cells that undergo the normal formylation process on expressed proteins are inhibited by compound 2A whereas, unformylated proteins, as produced in the cells grown under these conditions, are not inhibited by compound 2A demonstrates that compound 2A is likely to work by inhibiting the deformylation reaction carried out by PDF.

**2** *Treatment of bacteria with compound 2A leads to the accumulation of N-terminally blocked proteins.*

If the compounds of the invention do actually inhibit PDF *in vivo*, then a consequence of treatment of bacteria with compound 2 (Example 2, diastereomer A) will be the accumulation of N-formyl methionine at the N-terminus of newly synthesised proteins. Such proteins will be N-terminally blocked and will be unable to be used as a substrate for N-terminal sequencing by Edman degradation chemistry.

To test this hypothesis a desired protein is expressed in the presence or absence of the test compound. The protein is isolated, purified and then subjected to Edman degradation protein sequencing using techniques known to the person skilled in the art.

Bacterial cells transformed with an expression vector allowing expression of the human calpain small regulatory subunit, were grown to an  $\text{OD}_{600}$  of 0.6 and then subjected to IPTG to induce expression of the heterologous protein in the presence

of 200 $\mu$ M compound 2A, in the presence of 240 $\mu$ M carbenicillin or, in the presence of vehicle control for 2.5 hours. Protein extracts were separated by SDS-PAGE, the calpain subunit eluted and the protein sequence determined by Edman degradation chemistry using the ABI automated protein sequencer. Equal quantities of protein were sequenced. The inventors found that the yield of the compound 2A treated protein was significantly reduced by 85% compared to vehicle and carbenicillin treated controls.

Calpain small regulatory subunit was cloned from messenger RNA obtained from a gastric tumour biopsy using the InVitrogen Micro Fast Track™ mRNA isolation kit version 2.2 (catalogue number K1520-02). Copy DNA from this mRNA was synthesised using the Promega Riboclone™ cDNA synthesis system M-MLV-RT(H-), NotI (Promega, Catalogue number C1660) according to the manufactures instructions. Two oligonucleotide primers for use in the polymerase chain reaction (PCR) were synthesised by Applied Biosystems, Inc., Custom Services, based on the published calpain small subunit sequence (EMBL Accession number X04106).

The *HindIII*/*XhoI* calpain fragment was then cloned into *HindIII* and *XhoI* digested expression vector pET24d(+) from Novagen Inc, (Madison, WI, USA) using standard procedures. The ligation mixture was used to transform competent DH5 $\alpha$  cells (Life Technologies, Inc, Grand Island, NY, USACat # 18265-017). Colonies were selected by growth overnight at 37°C on YT plates plus 30 $\mu$ g/ml kanamycin. Plasmid DNA was prepared as using the Promega Plus SV miniprep kit and clones with the calpain insert were identified using standard procedures. The DNA sequence was confirmed using the PE Applied Biosystems cycle sequencing as described above.

The *E. coli* gene cloned in pET24d(+) (designated pET24-CANS) was used to transform BL21 DE3 cells from Novagen Inc, (Madison, Wisconsin). Clones were selected at 37°C on YT agar plates (8g/l typtone, 5g/yeast extract, NaCl 5g/l, agar 15g/l) supplemented with 30 $\mu$ g/ml kanamycin.

## Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☒ Claims Nos.:  
because they relate to subject matter not required to be searched by this Authority, namely:  
Remark: Although claim(s) 2,3,7-23,28  
is(are) directed to a method of treatment of the human/animal  
body, the search has been carried out and based on the alleged  
effects of the compound/composition.
2. ☒ Claims Nos.:  
because they relate to parts of the International Application that do not comply with the prescribed requirements to such  
an extent that no meaningful International Search can be carried out, specifically:  
see FURTHER INFORMATION sheet PCT/ISA/210
3. ☐ Claims Nos.:  
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

## Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

1. ☐ As all required additional search fees were timely paid by the applicant, this International Search Report covers all  
searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment  
of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this International Search Report  
covers only those claims for which fees were paid, specifically claims Nos.:
4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is  
restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest.  
☐ No protest accompanied the payment of additional search fees.
